APPARATUS FOR CONNECTING FLUID CONDUITS

This invention is in the field of fluid conduits such as are used to carry liquids and gases, and in particular an apparatus for connecting such conduits together or to various fittings in a
5 conduit network.

BACKGROUND

Sections of fluid conduit must be connected together, or to other fittings in a conduit network
10 to carry gases and liquids without leaking from the network. The fluid pressure varies from low pressure lines, such as sewage lines where the pressure is essentially atmospheric pressure, to higher pressure water lines and the like, up to very high pressure industrial lines where the pressure is 10,000 pounds per square inch (psi) or more.

15 Conventional conduit connections are made using a gasket that is essentially clamped and squeezed between hollow members attached to each conduit. The clamping force is exerted by bolts in a typical flange connection, by a threaded configuration on a typical pipe union, and like apparatuses.

20 For example in a typical flange connection, conventional gaskets are made from a material

- Page 2 -

that is softer than the flange material, typically metal, plastic, rubber, or the like. Sealing of the connection is accomplished by clamping the flanges very tightly together so that the gasket is squashed between the two flanges. Typically the clamping force is provided by several bolts through corresponding holes around the flanges. To ensure proper sealing the bolts must be tightened evenly to a high torque. The flanges must be strong enough to resist distortion under the clamping forces, and as a result such flanges are commonly heavy, costly, and cumbersome, especially for high pressure conduits.

Similarly in a pipe union the threaded members are tightened to squeeze the sealing faces. In some unions of this type a gasket is used, while in others no gasket is present and the metal faces alone provide the seal when squeezed together.

Conduit networks can comprise a large number of connections. Significant longitudinal forces are exerted on the conduits when the conventional connections are tightened to exert the required clamping force. These forces are transferred through the conduit network from each such connection, causing stress on the entire network. The network must be designed to accommodate these forces, and careful installation is required to avoid excessive stress and resulting failure of components

20 SUMMARY OF THE INVENTION

- Page 3 -

It is an object of the present invention to provide an apparatus for connecting conduits together, or to other conduit network components that overcomes disadvantages of the prior art connections. It is a further object of the present invention to provide such an apparatus
5 that reduces longitudinal forces exerted on connected conduits.

The present invention provides an apparatus having a gasket member that slides in a pocket on the face of a first flange, or like connecting member, and seals against the walls of the pocket with an o-ring or the like. A seal on the face of the gasket member opposite the first
10 connecting member seals against the face of a second flange. The flanges are clamped together by bolts, a threaded union, or the like. A bias element between the gasket member and the bottom of the pocket forces the seal on the face of the gasket against the face of the second flange. The clamping force can be reduced, since the seal is initially provided by the force of the bias element. The gasket member slides in the pocket, and ~~to the clamping force~~
15 is not translated to the seal on the face of the gasket member. The clamping force needs only to be sufficient to maintain the apparatus in position.

Once the conduits are pressurized with fluid, pressure inside the connection forces the seal on the face of the gasket member against the face of the second flange. Higher pressure exerts a
20 greater force with the result that the seal is maintained for a wide range of pressures.

- Page 4 -

Installation is simplified since the high torque and even clamping force required by conventional connections is not required by the apparatus of the invention. Stress on the conduit network is reduced since clamping forces and the resulting longitudinal forces
5 exerted on the conduits are reduced. Installation and design are simplified.

The invention also provides an apparatus for sealing two conventional flanges together, thus providing a substitute for a conventional soft gasket.

10 **DESCRIPTION OF THE DRAWINGS:**

While the invention is claimed in the concluding portions hereof, preferred embodiments are provided in the accompanying detailed description which may be best understood in conjunction with the accompanying diagrams where like parts in each of the several diagrams
15 are labeled with like numbers, and where:

Fig. 1 is a side view of an apparatus of the invention joining two conduits;

Fig. 1A is a schematic detail view of the spring bias elements;

20

- Page 5 -

Fig. 2 is a top view of the gasket member of the apparatus of Fig. 1;

Fig. 3 is a bottom view of the gasket member;

5 Fig. 4 is a top view of an alternate apparatus to provide a seal between two
conventional flat flanges;

Fig. 5 is a schematic cross-section through line 5-5 in Fig. 4.

10 **DETAILED DESCRIPTION OF THE ILLUSTRATED EMBODIMENTS:**

Fig. 1 illustrates an embodiment of the present invention for connecting conduits 1 and 2.
The connection comprises flat flange 3 and pocket flange 4 attached to respective ends of
conduits 1, 2. The same connection can be made where one of the flanges 3, 4 is attached to
15 a conduit that is incorporated in a T-fitting, an elbow, or any like component of a conduit
network.

Gasket member 10, as best seen in Figs. 2 and 3, is an annular ring of metal, or a like hard
material, with a groove around the periphery thereof to accommodate an outside o-ring 12,
20 and a groove in ring face 13 to accommodate an inner o-ring 14. The opposite flat face 15 of

- Page 6 -

the gasket member 10, illustrated in Fig. 3 is typically flat.

Flat flange 3 has a flat face 5 that bears against the inner o-ring 12. Pocket flange 4 defines a pocket 7 such that the gasket member 10 slides into the pocket 7 with the outer o-ring 12
5 sealing against the walls of the pocket 7. The flanges 3, 4 are clamped together with bolts 9, or like fasteners around the flanges 3, 4.

Conventional gasket members are made from a material that is softer than the flange material, typically metal, plastic, rubber, or the like. Sealing of the connection is
10 accomplished by tightening the bolts to a high torque so that the gasket is squashed between the two flanges. The bolts must also be tightened evenly to ensure proper sealing.

Sealing of the conduit connection of the invention does not depend on a high torque on the bolts 9 exerting a large clamping force. In fact the clamping force is not translated to the
15 gasket member 10 at all, since the gasket member 10 slides in the pocket 7. The seal of the invention is accomplished initially with bias elements, illustrated as springs 20, pushing against the flat face 15 of the gasket member 10 and causing the gasket member 10 to slide in the pocket 7 and thus force the inner o-ring 14 against the flat face 5 of the flat flange 3. The inner o-ring 14 seals against the flat face 5 of the flat flange 3, and the outer o-ring 12 seals
20 against the walls of the pocket 7, thereby sealing the connection.

- Page 7 -

Fig. 1A schematically illustrates the seating of a spring 20 in a recess 22 in the bottom of the pocket 7 in pocket flange 4. The bias force could also be provided by various other spring configurations, resilient members, or similar bias elements as are known in the art.

5

During start up, the seal between inner o-ring 14 and flat face 5 is maintained by the springs 20. As the pressure in the conduits 1, 2 builds, that pressure exerts a correspondingly increasing force urging the gasket member 10 towards the flat face 5 of the flat flange 3, as described below.

10

Between the outer and inner o-rings 12, 14 on the inside of the seal, the pressure HP is that of the fluid inside the connected conduits 1, 2. Between the o-rings 12, 14 on the outside of the seal, the pressure is that of the atmosphere surrounding the connection AP, typically much lower than the pressure HP inside the conduits 1, 2.

15

Thus the pressure HP is being exerted on that portion of the gasket member 10 indicated by A1 on the ring face 13, and A2 on the flat face 15. This is the area between the o-rings 12, 14 that is inside the connection, extending from the inner ring 14 to the inside bore 10B of the gasket member 10 (indicated by A1), along the walls of the bore 10B, and across the opposite flat face 15 to the outer edge of the gasket member 10 (indicated by A2) and then

20

- Page 8 -

along the outer wall to the outer o-ring 12.

That portion of the gasket member 10 that is outside the seal is exposed to lower atmospheric pressure AP. The outside portion extends from the outer o-ring 14 along the wall to the ring face 13 and along the ring face 13 from the outer edge thereof to the inner o-ring 12 (indicated by A3).

The force exerted on the flat face 15 of the gasket member 10 in direction F is a product of the total area A2 of the flat face 15 times the pressure HP, plus whatever force is exerted by the springs 20. The force exerted on the ring face 13 of the gasket member 10 in the direction opposite to F is a product of the area A1 of one portion of the ring face 13 times the pressure HP, plus the area A3 of the other portion of the ring face 13 times the atmospheric pressure AP.

The area A2 is approximately equal to the sum of the areas A1 and A3, discounting the width of the inner o-ring 14. After assembly and prior to pressurizing the connection, the pressure inside HP and outside AP is the same, and the forces resulting from pressure are equal. The force in direction F is then equal to the force of the springs 20. The force of the springs 20 is designed to provide sufficient force to maintain the seal via inner o-ring 14 between the gasket member 10 and the flat face 5 of the flat flange 3 during start up.

- Page 9 -

As the pressure HP builds, it can be seen that the force in direction F increases, since the higher pressure HP is being exerted on the areas A1 and A2. The area A2 is significantly greater than the area A1 resulting in a greater force in direction F, since the pressure AP on the area A3 remains constant. While the bolts 9 need not be highly torqued during installation, they must be strong enough to withstand the force F as the pressure HP builds to operating levels. The greater the pressure HP the greater the force F, thus maintaining the seal.

10 In some applications it may also be necessary to consider a situation where there is suction or vacuum on the conduits. Suction can sometimes develop when conduits are being drained for example. The pressure HP inside is then less than the atmospheric pressure AP. The strength of the springs 20 can be large enough to maintain the seal when the pressure HP is lower than the pressure AP, and the force exerted by the pressure AP on area A3 of the ring face 13 added to the force exerted on area A1 by the pressure HP is greater than the opposite force exerted by the pressure HP on the area A2. The pressure forces would then tend to move the ring face 13 and inner o-ring 14 away from the flat face 5 of the flat flange 3, thereby breaking the seal. Ensuring that the bias force exerted by the springs 20 is always larger than any such contemplated suction forces will ensure that the seal is maintained.

- Page 10 -

Depending on the pressures to be encountered in any particular application, the areas A1 and A3 can be adjusted by moving the inner o-ring 14.

5 Figs. 4 and 5 illustrate an alternate embodiment of the invention for use with a pair of conventional flat faced flanges. The apparatus 100 provides a substitute for a conventional gasket. A housing 102 forms a channel 107 that roughly corresponds to the pocket 7 of the prior embodiment. A gasket member 110 slides in the channel 107 and is sealed to the walls 107W of the channel 107 by an outer o-ring 112. Inner o-rings 14 on the gasket member 110 and housing 102 provide the seal between the flat flanges. A bias element, illustrated as
10 spring 120, exerts an initial force between the gasket member 110 and housing 102 so as to force them apart and exert equal and opposite forces F, F' on the flat flanges.

As above, when the pressure HP inside the connection rises above the atmospheric pressure AP, the force between the flat face 115 of the gasket member 110 and the housing 102 is
15 greater than the opposite forces on the ring face 113 and the bottom area A4 of the housing 102, and a sealing force in directions F, F' is exerted to seal the inner o-rings 114 against the flat flanges.

The foregoing is considered as illustrative only of the principles of the invention. Further,
20 since numerous changes and modifications will readily occur to those skilled in the art, it is

- Page 11 -

not desired to limit the invention to the exact construction and operation shown and described, and accordingly, all such suitable changes or modifications in structure or operation which may be resorted to are intended to fall within the scope of the claimed invention.
